red values are not defined for resistance thermometers with thin-film sensors

Please note:

The above values apply to Pt100 resistance thermometers.

A Pt100 resistance thermometer consists of the built-in Pt100 sensor, which is installed in a protective fitting equipped with a mechanical and electrical connection for protection.

As practice has shown, a Pt100 resistance thermometer does not necessarily have the accuracy class of the built-in Pt100 sensor. Other accuracy classes therefore apply to the built-in sensor.

When calculating the accuracy of a Pt100 resistance thermometer, it should also be noted that thin-film sensors show a different, temperature-dependent behavior at higher temperatures than wire-wound sensors. For this reason, different temperature ranges have been defined for Pt100 resistance thermometers with thin-film sensors and pt100 resistance thermometers with wire-wound sensors, in which the accuracy class is valid.

Calculation formula limit deviation class A:

$$t_F = \pm (0,15 + 0,002 * t)$$

t= measured temperature without sign (absolute value without + or -)

tF= measurement error in °C

Valid temperature range:

Resistance thermometer with thin-film sensor: from -30 to +300 °C

Resistance thermometer with wire-wound sensor: from -100 to +450 °C
